25 **Abstract**

26 B-cell progenitor fate determinant interferon regulatory factor 4 (IRF4) exerts key
27 roles in the pathogenesis and progression of multiple myeloma (MM), a currently
28 incurable plasma cell malignancy. Aberrant expression of IRF4 and the
29 establishment of a positive auto-regulatory loop with oncogene MYC, drives a
30 MM specific gene-expression programme leading to the abnormal expansion of
31 malignant immature plasma cells. Targeting the IRF4-MYC oncogenic loop has
32 the potential to provide a selective and effective therapy for MM. Here we
33 evaluate the use of bromodomain inhibitors to target the IRF4-MYC axis through
34 combined inhibition of their known epigenetic regulators, BRD4 and CBP/EP300.
35 Although all inhibitors induced cell death, we found no synergistic effect of
36 targeting both of these regulators on the viability of MM cell-lines. Importantly, for
37 all inhibitors over a time period up to 72 hours, we detected reduced IRF4 mRNA,
38 but a limited decrease in IRF4 protein expression or mRNA levels of downstream
39 target genes. This indicates that inhibitor-induced loss of cell viability is not
40 mediated through reduced IRF4 protein expression, as previously proposed.
41 Further analysis revealed a long half-life of IRF4 protein in MM cells. In support
42 of our experimental observations, gene network modelling of MM suggests that
43 bromodomain inhibition is exerted primarily through MYC and not IRF4. These
44 findings suggest that despite the autofeedback positive regulatory loop between
45 IRF4 and MYC, bromodomain inhibitors are not effective at targeting IRF4 in MM
46 and that novel therapeutic strategies should focus on the direct inhibition or
47 degradation of IRF4.

49 **Introduction**

50 Transcription factor IRF4 (interferon regulatory factor 4) is a key activator
51 of lymphocyte development, affinity maturation and terminal differentiation into
52 immunoglobulin-secreting plasma cells^{1,2}. Faulty regulation of IRF4 expression is
53 associated with numerous lymphoid malignancies, including multiple myeloma
54 (MM), an aggressive and incurable hematologic cancer characterized by the
55 abnormal proliferation of bone marrow plasma cells^{2,3}. At the molecular level MM
56 is an heterogenous disease with several subgroups defined by specific gene-
57 expression profiles and recurrent chromosomal rearrangements. In a minority of
58 MM cases, chromosomal translocation t(6;14)(p25;q32) brings the *IRF4* gene
59 under the control of immunoglobulin heavy-chain regulatory regions^{4,5}.
60 Interestingly while IRF4 is not always genetically altered in MM⁶, its expression
61 levels are always higher than in plasma cells⁷. Over-expression of IRF4 leads to
62 an aberrant gene-expression programme and to the mis-regulated transcription
63 of a wide network of target genes. IRF4 loss-of-function in RNA-interference-
64 based experiments have shown that MM cells are “addicted” to this abnormal
65 gene-expression programme since reduced IRF4 expression causes rapid and
66 extended non-apoptotic cell death, irrespective of genetic etiology⁶. Similarly,
67 targeting the 3' UTR of IRF4 mRNA for degradation by overexpression of miR-
68 125-b, leads to MM cell death⁸.
69 MM accounts for 2% of all cancers and 10% of all hematologic malignancies⁹. In
70 the UK around 5800 MM cases are diagnosed every year (2015-2017) and
71 incidence rates are projected to rise by 11% by 2035. The past decade has seen
72 a revolution in the management of MM with the availability of novel therapies

which are both more effective and less toxic. Despite the ensuing improvement of clinical outcomes, nearly every patient becomes refractory to therapies and overall 5-year survival rates are 52%¹⁰. Considering that existing treatments are not curative, there is a need for new therapeutic approaches. Targeting IRF4 has potential to be a powerful therapeutic strategy in MM. Firstly, IRF4 inhibition likely presents manageable side effects as phenotypes in IRF4-deficient mice are restricted to lymphoid and myeloid lineages and mice lacking one allele of IRF4 are phenotypically normal⁶. Additionally, MM cells' "addiction" to IRF4 renders them fairly sensitive to even small decreases in IRF4 levels leading to cell death. Finally, IRF4 inhibition is lethal to all MM cells regardless of their underlying transforming oncogenic mechanism⁶.

An attractive approach to inhibit IRF4 might be targeting a known regulator of IRF4 expression in MM, MYC. Constitutive activation of MYC signalling is detected in more than 60% of patient-derived cells and one of the most common somatic genomic aberrations in MM is rearrangement or translocation of MYC¹¹. MYC transactivates *IRF4* by binding to a conserved intronic region whilst IRF4 binds to the *MYC* promoter region in MM cells and transactivates its expression, creating a positive autoregulatory feedback loop⁶. The expression of MYC in MM cells is abnormal since normal plasma cells do not express MYC as a result of repression by PR domain zinc finger protein 1 (PRDM1)¹². Moreover, IRF4 binds to its own promoter region, creating a second positive autoregulatory loop which would potentiate any therapeutic effect of targeting the MYC-IRF4 loop⁶. The IRF4-MYC axis is thus considered to be a promising therapeutic target in MM,

however the complex regulatory feedbacks make predictable targeting of this axis challenging.

One way to target the IRF4-MYC axis is through upstream epigenetic regulators. Bromodomain and extra-terminal (BET) proteins inhibitors have emerged as potential therapeutic agents for the treatment of haematologic malignancies¹³. BET protein BRD4 is specifically enriched at immunoglobulin heavy chain (IgH) enhancers in MM cells bearing IgH rearrangement at the MYC locus, causing their aberrant proliferation¹⁴. BET inhibitors such as JQ1, which displace BRD4 from chromatin by competitively binding to its bromodomain acetyl-lysine recognition pocket, trigger inhibition of MYC transcription^{14,15}.

CREB binding protein (CBP) and EP300 are bromodomain-containing histone acetyltransferases¹⁶. CBP/EP300 bromodomain inhibitors, such as SGC-CBP30, induce cell cycle arrest and apoptosis in MM cell-lines¹⁷. Whilst the effects of BET bromodomain inhibition are most likely due to direct suppression of MYC, inhibition of CBP/EP300 bromodomain has been proposed to work through suppression of IRF4¹⁷.

Given the positive auto regulation loop between MYC and IRF4 in MM, we hypothesised that combining the two classes of inhibitors with distinct transcriptional effects would have a synergistic impact on MM cells. To confirm this, we explored the effect of combinations of BET and CBP/EP300 inhibitors on the viability of a panel of MM cell-lines. To assess whether the protein and mRNA levels for MYC, IRF4 and their downstream targets following drug exposure were consistent with those expected from the IRF4-MYC auto-regulatory loop model, we compared their experimentally measured with their simulated expression in a

120 network model of MM molecular interactions. We found that within the time
121 frames used there is no synergistic effect on the viability of MM cell-lines. For all
122 inhibitors we experimentally measured largely unaffected levels of IRF4 protein
123 and downstream target protein mRNA levels. These results are consistent with
124 the continued presence of IRF4 protein in MM cells due to its long half-life. Our
125 network modelling of MM therefore suggests that cell death induced by
126 CBP/EP300 bromodomain inhibition is not exerted directly through IRF4 but
127 indirectly through MYC.

128

129 **Methods**

130

131 **Cell viability assay**

132 Cell viability assay and statistical analysis were performed as described in the
133 supplemental methods. In brief, cell viability after inhibitors treatment was
134 assessed using CellTiter-Blue® Cell Viability Assay. Each experiment was
135 reproduced 3 times per cell line.

136

137 **Western Blotting**

138 Detailed protocols for western blotting are available in the supplemental methods.
139 Primary antibodies: IRF4 (ab133590, Abcam), MYC (sc-40, Santa-Cruz
140 Biotechnology) and β-actin (A2066, Sigma-Aldrich). HRP-conjugated secondary
141 antibodies: anti-rabbit (ab205718, Abcam) anti-mouse (7076S, Cell signalling).

142

143 **Quantitative Real Time PCR**

144 RNA extraction, cDNA synthesis, and quantitative real time PCR was performed
145 as in the supplemental methods.

146

147 **Protein half-life**

148 To measure protein half-life, cells were treated with 10 μ g/mL cycloheximide for
149 up to 72h followed by western blotting. Detailed protocols are available in the
150 supplemental methods.

151

152 **Gene and protein network modelling**

153 Computational models were constructed using Ordinary Differential Equations
154 and solved using MATLAB 2020a and ode15s. All code, equations and
155 parameters used in modelling are available on Github
156 (<https://github.com/SiFTW/MMModel/>). Regulated reactions were modelled as
157 described previously ¹⁸. Detailed methods are available in the supplemental
158 methods.

159

160 **Results**

161 **Concomitant BRD4 and CBP/EP300 inhibition does not have a synergistic
162 effect on MM cell viability**

163 To explore the effect of the combination of bromodomain inhibitors on MM cell
164 viability, we employed BET inhibitors JQ1 and OTX015, CPB/EP300 inhibitor
165 SGC-CBP30 and ISOX-DUAL, a dual inhibitor of BET and CPB/EP300. Three
166 MM (KMS-12-BM, NCI-H929, SKMM-1) and one acute leukaemia (OCI-AML3)
167 cells lines were treated for 48h with different concentrations of these compounds.

As shown in Fig.1a-e, JQ1 was the most effective inhibitor with an IC₅₀ between 0.27 and 0.42μM. Similar IC₅₀ values were obtained for OTX015 (0.47-1.9μM) and JQ1+SGC-CBP30 (0.28-0.67μM). However, treatment with SGC-CBP30 alone (IC₅₀ 1.58μM-5μM) and ISOX-DUAL (2.15μM-7.70μM) showed reduced efficacy. The poor inhibitory activity of ISOX-DUAL could be explained by its reduced affinity for BRD4 and CPB/EP300 (IC₅₀ 1.5 and 0.65μM) when compared to JQ1 and SGC-CBP30¹⁹. To test this hypothesis, we compared the effect of ISOX-DUAL treatment with a combination of JQ1+SGC-CBP30 (Fig.1e). We found that the combination treatment had a stronger inhibitory effect on cell viability than ISOX-DUAL, with an IC₅₀ comparable with that of JQ1 alone. Similar results were obtained when treating the cells for 72h (Fig. S1). Taken together, our results demonstrate that ISOX-DUAL offers no advantage to treatment with a BET inhibitor alone and that combining JQ1 and SGC-CBP30 does not lead to synergistic or antagonistic cytotoxic effects.

Bromodomain inhibitors impact IRF4 mRNA but not protein expression in

MM cell-lines

We next investigated the effects of bromodomain inhibitors on the mRNA and protein expression levels of IRF4 and MYC. We treated the cells with a concentration of drugs at their IC₅₀ value (as in Fig.1). As shown by western blotting analysis, we observed a dramatic decrease in the level of MYC protein, following treatment for 4, 8, 24h (Fig.S2) with a complete abrogation after 48h and 72h (Fig.2) However, drug treatments did not have a similar effect on IRF4 protein levels. No reduction in IRF4 protein levels was observed at any of the

time points when using JQ1 or OTX015 and a slight reduction in IRF4 protein expression (up to 30%) was only observed across all MM cell-lines when a combination JQ1+SGC-CBP30 was used (Fig.2, S2). We next examined the effect of drug treatment on the levels of *IRF4* and *MYC* mRNA. Treatment with all drugs significantly decreased both *IRF4* and *MYC* mRNA expression in all cell-lines after 4, 8, 24, 48 and 72h (Fig.3, S3), although the mean reduction for *MYC* was more pronounced than that for *IRF4*. In summary, our data show that bromodomain inhibitors effectively reduce *MYC* and *IRF4* mRNA levels and *MYC* protein levels, but do not show a corresponding effect on *IRF4* protein levels.

Bromodomain inhibitors affect the gene-expression levels of target genes of *MYC* but not *IRF4*

As protein levels of *MYC* and *IRF4* were unequally affected by drug treatment, we hypothesised that expression of their downstream target genes would also be differentially affected. To test this hypothesis, we measured the impact of drug treatment on the mRNA levels of *IRF4* (*KLF2* and *PRDM1*) and *MYC* (*CDK4* and *hTERT*) downstream targets. We treated the cells with a concentration of drugs corresponding to their IC₅₀ value for 4, 8, 24, 48 and 72h (Fig.4, S6, S7). At the early time points of 4, 8 and 24h, no significant reduction of mRNA levels could be detected in the MM cell-lines for *IRF4* downstream target *KLF2* (Fig.S4), whilst a 30% reduction could be seen after 48 and 72h (Fig.4). A similar trend was observed for *PRDM1* mRNA levels, with small decreases at early time points (Fig.S4) and more substantial decreases of about 50% only occurring after 48 and 72h (Fig.4).

216 In contrast, mRNA expression of the MYC downstream targets *hTERT* and *CDK4*
217 were rapidly and effectively decreased by drug treatment in all cell-lines (Fig.5,
218 S5).

219 In summary, these results confirm our hypothesis that MYC, but not IRF4
220 downstream target genes are substantially downregulated as a result of
221 bromodomain inhibition.

222

223 **Gene and protein network modelling are consistent with a long IRF4 protein
224 half-life**

225 Given the known feedback loop between MYC and IRF4 in MM cells we asked
226 whether the reduction in IRF4 mRNA, but not protein expression could be
227 explained by the stability of IRF4 protein.

228 To test this hypothesis and to assess whether the protein and mRNA levels for
229 MYC, IRF4 and their downstream targets following drug exposure were
230 consistent with those expected from the IRF4-MYC auto-regulatory loop model,
231 we used computational techniques to model the MYC and IRF4 gene and protein
232 network in MM cells. Computational modelled time courses of PRDM1, IRF4, and
233 MYC protein and mRNA levels were generated by simulating the effect of
234 inhibiting MYC mRNA transcription. In order to compare computational
235 simulations with measured protein and mRNA levels, both experimental and
236 simulated results were normalised to the first timepoint to give a fold change over
237 time.

238 As the results are independent from the drug and cell line used, we initially
239 modelled our response based on drugs inhibiting MYC expression (Fig.6a) using

the published half-life for MYC of 30min²⁰ and an estimated of 7h for IRF4 (no data was found). The squared distance between the mean experimental result and modelled response for each timepoint shows a discrepancy, specifically for IRF4 protein and PRDM1 mRNA levels (Fig.6b), suggesting that IRF4 has a half-life significantly longer than 7 h. To measure IRF4 protein half-life, we treated MM cell-lines with 10µg/mL cycloheximide to block protein synthesis for up to 72h and monitored the effect on existing protein levels by western blotting (Fig.7a). We found that IRF4 protein levels decreased slowly in all MM cell-lines and the half-life was determined to be 61, 52 and 33h in KMS-12-BM, NCI-H929 and SKMM-1 respectively. In contrast to the stability of IRF4, levels of MYC decreased within 30min in all MM cell-lines, (half-lives of 1hr, 22min and 30min respectively), in line with published reports²⁰. To test whether a half-life of 48h for IRF4 can explain the observed response to the drug we modelled MYC and IRF4 gene and protein network using this longer half-life. The squared distance between the mean experimental result and modelled response for each timepoint now shows a good agreement between the model and the data (Fig.7b). Despite the overall improvement of the fit, a discrepancy persists for IRF4 protein levels between 24 and 36h suggesting that the model does not completely recapitulate the data, especially at the later time points.

Gene and protein network modelling suggest that bromodomain inhibitors effects on MM cell-lines are mainly exerted through MYC transcription repression and not IRF4

The initial computational modelling of the predicted drug response on MM cell-lines was formulated on the assumption of bromodomain inhibition affecting mainly MYC transcription. This was a reasonable assumption based on the observation that unperturbed IRF4 protein levels in MM cell-lines could be measured following most drug treatment. However, because of a small (30%) but consistent reduction of IRF4 protein levels in response to treatment with the JQ1+ SGC-CBP30 combination we then asked whether bromodomain inhibitors work through repression of MYC, IRF4 or both. To do so, we used gene and protein network modelling to simulate the effect of a drug acting on the transcription of MYC, IRF4 or both (Fig.8a) using the measured half-lives of IRF4 and MYC. When comparing the predicted to the experimentally measured expression of MYC, IRF4 and PRDM1 we could conclude that the main effect of the drugs is predicted to be through disruption of MYC transcription (Fig.8b). The modelled response of the effects of a drug acting only on IRF4 transcription poorly predicts the observed protein and mRNA levels, especially those of MYC. Simulating the effects of a drug treatment targeting both MYC and IRF4 transcription improves the match, but not as well when using a single-hit to MYC model. However, for all models a discrepancy remains between the measured and modelled levels of IRF4 protein after 24h, pointing at additional and yet uncovered regulatory interactions within the IRF4 network in MM cells. When extrapolated to MM cells *in vivo*, our work has important implications for the design of new therapeutic strategies.

285

286 **Discussion**

287 In this work we studied the effects on MM cell-lines of two classes of
288 bromodomain (BET and CBP/Ep300) inhibitors, with putatively distinct
289 transcriptional effects, with the aim to disrupt the oncogenic feedback loop
290 between MYC and IRF4. Specifically, we wanted to evaluate the possibility that
291 the combination of these bromodomain inhibitors would have synergistic impact
292 on the viability of MM cells and on the transcription and protein levels of IRF4 and
293 MYC.

294 Our data showed that while the two BET inhibitors JQ1 and OTX015 showed the
295 most effective inhibition on cell viability, the CBP/Ep300 inhibitor SGC-
296 CBP/Ep300 and the dual BET-CBP/Ep300 inhibitor ISOX-DUAL caused the least
297 effect. Since the combination JQ1+SGC-CBP30 has a stronger inhibitory effect
298 on cell viability compared to the dual inhibitor alone this suggests that the limited
299 effect of ISOX-DUAL is caused by its reduced affinity for BRD4 and CPB/EP300.
300 Our data also indicate that combining JQ1 and SGC-CBP30 does not lead to
301 synergistic or antagonistic cytotoxic effects on MM cell-lines. In line with previous
302 studies^{14,15,17,22}, we found that these drugs cause MYC downregulation at protein
303 and mRNA levels. Interestingly, within the time frame and for all inhibitors we
304 have observed largely unaffected levels of IRF4 protein and downstream target
305 gene mRNA levels. Using computational modelling of a network of MM molecular
306 interactions, we could show that these results can be partially explained by the
307 high stability of the IRF4 protein (>48h). Finally, the modelling data also implies
308 that any effect observed on MM cell-lines for both inhibitors is not exerted through
309 IRF4 but mainly through MYC. These results are in contrast with previous data¹⁷
310 supporting the idea that SGC-CBP30 treatment on MM cell line causes cell

311 cytotoxicity via targeting of IRF4. However, more recent data show that inhibition
312 of CBP/EP300 bromodomains can interfere with GATA1 and MYC-driven
313 transcription by displacing CBP/EP300 from GATA1 and MYC binding sites at
314 enhancers leading to a decrease in the level of acetylation of these regulatory
315 regions. This in turn reduces gene-expression of both GATA1 and MYC²³.

316 Our data shows that IRF4 is characterized by a long half-life in a panel of MM
317 cell-lines. Previous studies have shown a variability in the half-life's values for
318 IRF proteins (IRF1~30min, IRF7~5h, IRF2~8h, IRF3~60h)^{24,25}. The basis of
319 these varied half-lives is unclear, but it may involve differences in ubiquitin-
320 mediated degradation through differential in expression of ubiquitin-specific
321 proteases (USPs). Alterations of USP enzymes are implicated in the
322 pathogenesis of various cancers and USP15 has been reported to be
323 overexpressed in MM cells and inhibit MM apoptosis^{26,27}. Interestingly, USP4
324 interacts with, stabilizes and deubiquitinates IRF4²⁸, which could provide an
325 explanation for the long IRF4 half-life. Further work will be required to determine
326 if these USPs have any role in the regulation of IRF4 stability in MM cells.

327 A growing body of preclinical and clinical evidence suggests that bromodomain
328 inhibition could be an important therapeutic approach in a number of hematologic
329 malignancies²⁹. Furthermore, *in vivo* and *in vitro* evidence suggests synergistic
330 cytotoxicity of bromodomain inhibitors and immunomodulatory drugs (IMiDs) in
331 MM³⁰ and primary effusion lymphoma³¹. IMiDs are known to bind cereblon,
332 which activates E3-ubiquitin ligase resulting in the degradation of IKZF1 and
333 IKZF3³². Downregulation of IKZF1 and IKZF3 then suppresses IRF4
334 transcription. Therefore IMiDs, just like bromodomain inhibitors, indirectly inhibit

335 IRF4 expression. Our studies suggest that indirect inhibition of IRF4, either via
336 IMiDs or bromodomain inhibition, might not be effective at interfering with IRF4
337 and its oncogenic transcription programme in MM because of its stability. Future
338 work aimed at targeting the IRF4 addiction in MM may be more effective if re-
339 focussed on direct inhibition or degradation of IRF4, which could be then used in
340 synergistic combination to address relapsed or refractory cases of MM for which
341 presently limited choices exist.

465 **DUAL and JQ1+ SGC-CBP30 treatments on MM cell-lines viability.**

466 Reduction of KMS-12-BM **(a)**, NCI-H929 **(b)**, SKMM-1 **(c)** and OCI-AML3 **(d)** cell
467 viability after treatment with different concentrations of bromodomain inhibitors
468 for 48h. Cell survival is plotted against the logarithm of inhibitor concentrations.
469 JQ1 (red curves), JQ1+SGC-CBPEP30 (purple curves), OTX015 (pink curves),
470 SGC-CBP30 (brown curves) and ISOX-DUAL (light blue curves). Results are
471 represented as mean \pm Standard Error of Mean (SEM) of triplicate assays. **(e)**
472 The graph shows the IC₅₀ values of JQ1, JQ1+SGC-CBP30, OTX015, SGC-
473 CBP/EP30, ISOX-DUAL after 48h treatment of KMS-12-BM (green bars), NCI-
474 H929 (black bars), OCI-AML3 (blue bars) and SKMM-1 (orange bars) cells.
475

476 **Figure 2. IRF4 and MYC protein levels in MM cell-lines following treatment**
477 **with JQ1, OTX015, SGC-CBP30, ISOX-DUAL and JQ1+ SGC-CBP30.**

478 Changes in MYC and IRF4 protein levels were analysed by Western Blot
479 following IC₅₀ drug treatments for 48 and 72h in KMS-12-BM, SKMM-1, NCI-
480 H929 and OCI-AML3. The control (CTRL) is 2mM DMSO treatment. β -actin was
481 used as loading control. Quantification was performed by using LI-COR machine
482 and protein levels were expressed relative to the control treatment.
483

484 **Figure 3. IRF4 and MYC mRNA expression in MM cell-lines following**
485 **treatment with JQ1, OTX015, SGC-CBP30, ISOX-DUAL and JQ1+ SGC-**
486 **CBP30.**

487 IRF4 and MYC mRNA expression was analysed by qPCR following IC₅₀ drug
488 treatments for 48 and 72h in KMS-12-BM (green bars), SKMM-1 (orange bars),
489 NCI-H929 (black bars) and OCI-AML3 (blue bars) cells. The control (CTRL) is
490 2mM DMSO treatment. Transcript levels were normalised against β-actin
491 expression and expressed relative to the control treatment. Data are shown as
492 mean ±SEM. A t-test was performed with reference to the control. *P<0.05,
493 **P<0.01, ***P < 0.001.

494 **Figure 4. IRF4 downstream gene mRNA expression in MM cell-lines**
495 **following treatment with JQ1, OTX015, SGC-CBP30, ISOX-DUAL and JQ1+**
496 **SGC-CBP30.**

497 KLF2 and PRDM1mRNA expression was analysed by qPCR following IC₅₀ drug
498 treatments for 48 and 72h in KMS-12-BM (green bars), SKMM-1 (orange bars),
499 and NCI-H929 (black bars) cells. The control (CTRL) is 2mM DMSO treatment.
500 Transcript levels were normalised against β-actin expression and expressed
501 relative to the control treatment. Data are shown as mean ±SEM. A t-test was
502 performed with reference to the control. *P<0.05, **P<0.01, ***P < 0.001.

503
504 **Figure 5. MYC downstream gene mRNA expression in MM cell-lines**
505 **following treatment with JQ1, OTX015, SGC-CBP30, ISOX-DUAL and JQ1+**
506 **SGC-CBP30.**

507 CDK4 and hTERT mRNA expression was analysed by qPCR following IC₅₀ drug
508 treatments for 48 and 72h in KMS-12-BM (green bars), SKMM-1 (orange bars),
509 and NCI-H929 (black bars) cells. The control (CTRL) is 2mM DMSO treatment.
510 Transcript levels were normalised against β-actin expression and expressed

511 relative to the control treatment. Data are shown as mean \pm SEM. A t-test was
512 performed with reference to the control. *P<0.05, **P<0.01, ***P < 0.001.

513

514 **Figure 6. Computational model of the molecular regulatory network in MM**
515 **cells.**

516 **(a)** Systems Biology Graphical Notation (SBGN) diagram of the model of IRF4,
517 MYC and PRDM1 regulation. Positive regulation is indicated by lines capped with
518 circles. Negative regulation is indicated by lines capped with bars. **(b)**
519 Experimentally measured expression of the indicated molecular species in H929,
520 SKMM-1, KMS cell-lines exposed to SGC-CBP30, JQ1, OTX015, ISOX-DUAL,
521 and JQ1+SGC-CBP30 combination. Each shaded region represents the
522 standard deviation of 3 experimental replicates. The modelled response is shown
523 with a solid line. The model assumes a half-life for IRF4 of 7 h. The squared
524 distance between the mean experimental result and modelled response for each
525 timepoint is shown in the bottom right with colours consistent with other panels.

526

527 **Figure 7. Analysis of IRF4 stability in MM cell-lines and updated**
528 **computational model of the molecular regulatory network in MM cell .**

529 **(a)** KMS-12-BM, SKMM-1, NCI-H929 were incubated with 10 μ g/mL
530 cycloheximide for the indicated time points and cell lysates analysed by Western
531 blotting for protein levels of IRF4 and MYC. β -actin was used as a loading control.

532 **(b)** Experimentally measured expression of the indicated molecular species in
533 H929, SKMM-1, KMS cell-lines exposed to SGC-CBP30, JQ1, OTX015, ISOX-
534 DUAL, and JQ1+SGC-CBP30 combination. Each shaded region represents the

535 standard deviation of 3 experimental replicates. The modelled response is shown
536 with a solid line. The model uses the experimentally determined IRF4 half-life.
537 The squared distance between the mean experimental result and modelled
538 response for each timepoint is shown in the bottom right with colours consistent
539 with other panels.

540

541 **Figure 8. Computational model simulating the effect of a drug acting on**
542 ***MYC* transcription, *IRF4* transcription or both.**

543 Systems Biology Graphical Notation (SBGN) diagram of the model of IRF4,
544 MYC and PRDM1 regulation. Positive regulation is indicated by lines capped with
545 circles. Negative regulation is indicated by lines capped with bars. Drugs are
546 shown impacting IRF4 transcription (A) and MYC transcription (B).
547 Experimentally measured expression of the indicated molecular species in H929,
548 SKMM-1, KMS cell-lines exposed to SGC-CBP30, JQ1, OTX015, ISOX-DUAL,
549 and JQ1+SGC-CBP30 combination. The impact of single targeting IRF4 (A, left)
550 and MYC (B, middle) is shown, along with the combination (A+B, right). Each
551 shaded region represents the standard deviation of 3 experimental replicates.
552 The modelled response is shown with a solid line. The model uses the
553 experimentally determined IRF4 half-life. The squared distance between the
554 mean experimental result and modelled response for each timepoint is shown in
555 the bottom right with colours consistent with other panels.
